

**STRAY-FIELD MEASUREMENTS ON B2 DIPOLES,  
EPB QUADS, AND VERNIER MAGNETS**

A. Weitsch

Stanford, California

December 4, 1972

This note contains information on the stray field at the ends of the magnets around the coils. The measurements were done in order to find a safe distance or the necessary shielding to operate magnetic field sensitive equipment like photomultipliers. Consequently, the measurements have only moderate accuracy (field  $\pm 5\%$   $\pm 5$  G, field direction  $\pm 10^\circ$ , positioning of probe  $\pm 0.25$  in.). In all cases both the vertical and horizontal symmetry planes were mapped. If the field direction is not fixed by symmetry, direction and absolute value is given in the graphs. The following measurements were made:

EPB Quadrupole at 100 A dc excitation  
No magnetic shielding (Fig. 1)

Vernier magnet at 100 A dc excitation  
with and without shielding plate (Figs. 2 and 3)

B2 (main ring) dipole pulsed to 4800 A, 18 kG.  
The field was measured at the flat top. Due to the asymmetric coil arrangement without shielding, the full vertical plane was measured (Fig. 4) and half the horizontal plane (Fig. 5). With the shielding plate the measurements were disturbed by remanent field effects in the plate and eddy currents in the plate, both having different time behavior and different space distributions from the field due to the primary excitation. The field map with the shielding plate (Fig. 6) has therefore only indicative value.
